

Certificate of Grant of Patent

Patent Number: GB2417273

Proprietor(s): Enventure Global Technology

Inventor(s): Brock W Watson
David P Brisco

This is to Certify that, in accordance with the Patents Act 1977,

a Patent has been granted to the proprietor(s) for an invention entitled
"Collapsible expansion cone" disclosed in an application filed **12 June 2003**.

Dated 11 October 2006

COLLAPSIBLE EXPANSION CONE**Cross Reference To Related Applications**

The present application claims the benefit of the filing dates of (1) U.S. provisional patent application serial no. 60/387,961, attorney docket no. 25791.108,

- 5 filed on 6/12/2002, which is a continuation-in-part of U.S. provisional patent application serial no. 60/363,829, attorney docket no. 25791.95, filed on 3/12/2002, the disclosures of which are incorporated herein by reference.

The present application is related to the following: (1) U.S. patent application serial no. 09/454,139, attorney docket no. 25791.03.02, filed on 12/3/1999, (2) U.S. patent application serial no. 09/510,913, attorney docket no. 25791.7.02, filed on 2/23/2000, (3) U.S. patent application serial no. 09/502,350, attorney docket no. 25791.8.02, filed on 2/10/2000, (4) U.S. patent application serial no. 09/440,338, attorney docket no. 25791.9.02, filed on 11/15/1999, (5) U.S. patent application serial no. 09/523,460, attorney docket no. 25791.11.02, filed on 3/10/2000, (6) U.S. patent application serial no. 09/512,895, attorney docket no. 25791.12.02, filed on 2/24/2000, (7) U.S. patent application serial no. 09/511,941, attorney docket no. 25791.16.02, filed on 2/24/2000, (8) U.S. patent application serial no. 09/588,946, attorney docket no. 25791.17.02, filed on 6/7/2000, (9) U.S. patent application serial no. 09/559,122, attorney docket no. 25791.23.02, filed on 4/26/2000, (10) PCT patent application serial no. 10 no. 60/3318,386, attorney docket no. 25791.67.02, filed on 9/10/2001, (29) U.S. utility patent application serial no. 09/969,922, attorney docket no. 25791.69, filed on 10/3/2001, (30) U.S. utility patent application serial no. 10/016,467, attorney docket no. 25791.70, filed on 12/10/2001; (31) U.S. provisional patent application serial no. 60/343,674, attorney docket no. 25791.68, filed on 12/27/2001; (32) U.S. provisional
15 patent application serial no. 60/346,309, attorney docket no. 25791.92, filed on 1/7/2002; (33) U.S. provisional patent application serial no. 60/372,048, attorney docket no. 25791.93, filed on 4/12/2002; (34) U.S. provisional patent application serial no. 60/363,829, attorney docket no. 25791.95, filed on 3/13/2002; (35) U.S. provisional patent application serial no. 60/372,632, attorney docket no. 25791.101, filed on
20 4/15/2002; (36) U.S. provisional patent application serial no. 60/380,147, attorney docket no. 25791.104, filed on 5/6/2002; and (37) U.S. provisional patent application serial no. 60/387,486, attorney docket no. 25791.107, filed on 6/10/2002, the disclosures of which are incorporated herein by reference.

This invention relates generally to oil and gas exploration, and in particular to
25 forming and repairing wellbore casings to facilitate oil and gas exploration.

Background Of The Invention

Conventionally, when a wellbore is created, a number of casings are installed in the borehole to prevent collapse of the borehole wall and to prevent undesired outflow of drilling fluid into the formation or inflow of fluid from the formation into the borehole.
30 The borehole is drilled in intervals whereby a casing which is to be installed in a lower borehole interval is lowered through a previously installed casing of an upper borehole interval. As a consequence of this procedure the casing of the lower interval is of smaller diameter than the casing of the upper interval. Thus, the casings are in a nested arrangement with casing diameters decreasing in downward direction. Cement

annuli are provided between the outer surfaces of the casings and the borehole wall to seal the casings from the borehole wall. As a consequence of this nested arrangement a relatively large borehole diameter is required at the upper part of the wellbore. Such a large borehole diameter involves increased costs due to heavy casing handling

5 equipment, large drill bits and increased volumes of drilling fluid and drill cuttings. Moreover, increased drilling rig time is involved due to required cement pumping, cement hardening, required equipment changes due to large variations in hole diameters drilled in the course of the well, and the large volume of cuttings drilled and removed.

10 The present invention is directed to overcoming one or more of the limitations of the existing procedures for forming new sections of casing in a wellbore.

Summary of the Invention

According to the present invention there is provided a packer cup apparatus comprising:

15 a central mandrel,
a sealing cup comprising
a substantially unrestricted lip for sealingly engaging a tubular member; and
a base portion for sealingly engaging the central mandrel,
a thimble positioned longitudinally along the central mandrel and surrounding the
20 base portion of the sealing cup,

a pliant backup member positioned between the protecting member and the sealing cup,
a conical bushing positioned partially between the sealing cup and the central mandrel for supporting the base portion of the sealing cup,

25 wherein the sealing cup further comprises an unsupported portion between the thimble and a point of engagement with the expandable tubular member, and a means for reducing the unsupported portion of the sealing cup

Preferably, the pliant backup member is made from a material selected from the group consisting of fluoropolymer, fluoroelastomer, Teflon, or PEEK.

30 Preferably, the apparatus further comprises a restraining member surrounding the base portion of the sealing cup for restraining the sealing cup.

Brief Description of the Drawings

Fig. 1a is a fragmentary cross-sectional illustration of the placement of a portion of an exemplary embodiment of an apparatus for radially expanding and plastically deforming a tubular member that includes a collapsible expansion cone within a preexisting structure.

Fig. 1b is a fragmentary cross-sectional illustration of another portion of the apparatus of Fig. 1a.

Figs. 2a and 2b are fragmentary cross-sectional illustration of a portion of the apparatus of Figs. 1a and 1b.

Fig. 3 is a fragmentary cross-sectional illustration of a portion of the apparatus of Figs. 1a and 1b.

Detailed Description of the Illustrative Embodiments

Referring to Figs. 1a, 1b, 2a, 2b, 3, 3a, 4, 4a, 5, 6, 7a, 7b, 7c, 7d, 7e, 7f, 8a, 8b, 8c, 8d, 8e, and 9, an exemplary embodiment of an apparatus 10 for radially expanding 20 and plastically deforming a tubular member includes a tubular support member 12 that defines a passage 12a. An end of the tubular support member 12 is coupled to an end of a safety collar 14 that defines a passage 14a, a recess 14b at one end for receiving the end of the tubular support member, and recesses 14c and 14d at another end.

A torque plate 16 is received within and is coupled to the recess 14c of the 25 safety collar 14 that defines a passage 16a and a plurality of meshing teeth 16b at one end. An end of an upper mandrel collar 18 is received within and is coupled to the recess 14d of the safety collar 14 proximate and end of the torque plate 16 that defines a passage 18a. Torque pins 20a and 20b further couple the end of the upper mandrel collar 18 to the end of the safety collar 14.

An end of an upper mandrel 22 is received within and is coupled to the upper 30 mandrel collar 18 that defines a passage 22a, a plurality of meshing teeth 22b that mate with and transmit torque to and from the meshing teeth 16b of the torque plate 16; and an external flange 22c at another end.

- An upper cup seal or packer cup 24 mates with, receives and is coupled to the upper mandrel 22 proximate the end of the upper mandrel collar 18. An upper spacer sleeve 26 mates with, receives, and is coupled to the upper mandrel 22 proximate an end of the upper packer cup 24. A lower cup seal or packer cup 28 mates with,
5 receives and is coupled to the upper mandrel 22 proximate an end of the upper spacer sleeve 26. In an exemplary embodiment, the packer cups 24 and 28 may be Guiberson™ packer cups. One embodiment of a Guiberson packer cup is discussed in detail below in reference to Fig. 18. Alternative embodiments of packer cups 24 and 28 are discussed below in reference to Figs. 19a-19e.
- 10 Turning back to Fig. 1, a lower spacer sleeve 30 mates with, receives, and is coupled to the upper mandrel 22 proximate an end of the lower packer cup 28 and the external flange 22c of the upper mandrel. A retaining sleeve 32 mates with, receives, and is coupled to an end of the lower spacer sleeve proximate the external flange 22c of the upper mandrel 22.
- 15 An end of a lower mandrel 34 defines a recess 34a that mates with, receives, and is coupled to the external flange 22c of the upper mandrel 22, a recess 34b that mates with, receives, and is coupled to the end of the upper mandrel, a passage 34c, and an external flange 34d including circumferentially spaced apart meshing teeth 34da on an end face of the external flange. Torque pins 36a and 36b further couple
20 the recess 34a of the end of the lower mandrel 34 to the external flange 22c of the upper mandrel 22. During operation, the torque pins 36a and 36b transmit torque loads between the recess 34a of the end of the lower mandrel 34 and the external flange 22c of the upper mandrel 22.
- An upper cam assembly 38 includes a tubular base 38a for receiving and
25 mating with the lower mandrel 34 that includes an external flange 38aa, a plurality of circumferentially spaced apart meshing teeth 38b that extend from one end of the tubular base in the longitudinal and radial directions for engaging the meshing teeth 34da of the end face of the external flange 34d of the lower mandrel, and a plurality of circumferentially spaced apart cam arms 38c that extend from the other end of the
30 tubular base in the opposite longitudinal direction and mate with and receive the lower mandrel. During operation, the meshing teeth 34da of the end face of the external flange 34d of the lower mandrel 34 transmit torque loads to the meshing teeth 38b of the upper cam assembly 38. Each of the cam arms 38c include an inner portion 38ca extending from the tubular base 38a that has arcuate cylindrical inner and outer

surfaces, 38caa and 38cab, a tapered intermediate portion 38cb extending from the inner portion that has an arcuate cylindrical inner surface 38cba and an arcuate conical outer surface 38ccb, and an outer portion 38cc extending from the intermediate portion that has arcuate cylindrical inner and outer surfaces, 38cca and 38ccb. In an exemplary embodiment, the radius of curvatures of the arcuate outer cylindrical surfaces 38cab are greater than the radius of curvatures of the arcuate outer cylindrical surfaces 38ccb. In an exemplary embodiment, the radius of curvatures of the arcuate inner cylindrical surfaces, 38caa, 38cba, and 38cca are equal.

A lower cam assembly 40 includes a tubular base 40a for receiving and mating with the lower mandrel 34 that includes an external flange 40aa, a plurality of circumferentially spaced apart meshing teeth 40b that extend from one end of the tubular base in the longitudinal and radial directions, and a plurality of circumferentially spaced apart cam arms 40c that extend from the other end of the tubular base in the opposite longitudinal direction and mate with and receive the lower mandrel. Each of the cam arms 40c include an inner portion 40ca extending from the tubular base 40a that has arcuate cylindrical inner and outer surfaces, 40caa and 40cab, a tapered intermediate portion 40cb extending from the inner portion 40ca that has an arcuate cylindrical inner surface 40cba and an arcuate conical outer surface 40ccb, and an outer portion 40cc extending from the intermediate portion that has arcuate cylindrical inner and outer surfaces, 40cca and 40ccb. In an exemplary embodiment, the radius of curvatures of the arcuate outer cylindrical surfaces 40cab are greater than the radius of curvatures of the arcuate outer cylindrical surfaces 40ccb. In an exemplary embodiment, the radius of curvatures of the arcuate inner cylindrical surfaces, 40caa, 40cba, and 40cca are equal. In an exemplary embodiment, the upper and lower cam assemblies, 38 and 40, are substantially identical. In an exemplary embodiment, the cam arms 38c of the upper cam assembly 38 interleave the cam arms 40c of the lower cam assembly 40. Furthermore, in an exemplary embodiment, the cam arms 38c of the upper cam assembly also overlap with the cam arms 40c of the lower cam assembly 40 in the longitudinal direction thereby permitting torque loads to be transmitted between the upper and lower cam assemblies.

An end of an upper retaining sleeve 42 receives and is threadably coupled to the external flange 34d of the lower mandrel 34 that defines a passage 42a for receiving and mating with the outer circumferential surfaces of the external flange 38aa and the meshing teeth 38b of the upper cam assembly 38, and an inner annular recess

42b, and includes an internal flange 42c for retaining the external flange 38aa of the upper cam assembly, and an internal flange 42d at one end of the upper retaining sleeve that includes a rounded interior end face. An o-ring seal 44 is received within the annular recess 42b for sealing the interface between the upper retaining sleeve 42
5 and the external flange 38d of the lower mandrel 34. A disc shaped shim 43 is positioned within the upper retaining sleeve 42 between the opposing end faces of the internal flange 42c of the retaining sleeve and the meshing teeth 38b of the upper cam assembly 38.

A plurality of upper expansion cone segments 44 are interleaved among the
10 cam arms 38c of the upper cam assembly 38. Each of the upper expansion cone segments 44 include inner portions 44a having arcuate cylindrical inner surfaces, 44aaa and 44aab, and an arcuate cylindrical outer surface 44ab, intermediate portions 44b extending from the interior portions that have an arcuate conical inner surface 44ba and arcuate cylindrical and spherical outer surfaces, 44bba and 44bbb, and outer
15 portions 44c having arcuate cylindrical inner and outer surfaces, 44ca and 44cb. In an exemplary embodiment, the outer surfaces 44ab of the inner portions 44a of the upper expansion cone segments define hinge grooves 44aba that receive and are pivotally mounted upon the internal flange 42d of the upper retaining sleeve 42.

The arcuate inner cylindrical surfaces 44aaa mate with and receive the lower
20 mandrel 34, the arcuate inner cylindrical surfaces 44aab mate with and receive the arcuate cylindrical outer surfaces 40ccb of the outer portions 40cc of the corresponding cam arms 40c of the lower cam assembly 40, and the arcuate inner conical surfaces 44ba mate with and receive the arcuate conical outer surfaces 40cbb of the intermediate portions 40cb of the corresponding cam arms of the lower cam assembly.

25 In an exemplary embodiment, the radius of curvature of the arcuate cylindrical inner surface 44aaa is less than the radius of curvature of the arcuate cylindrical inner surface 44aab. In an exemplary embodiment, the radius of curvature of the arcuate cylindrical inner surface 44ca is greater than the radius of curvature of the arcuate cylindrical surface 44aab. In an exemplary embodiment, the arcuate cylindrical inner surfaces, 44aaa and 44aab, are parallel. In an exemplary embodiment, the arcuate cylindrical outer surface 44ab is inclined relative to the arcuate cylindrical inner surface 44aaa. In an exemplary embodiment, the arcuate cylindrical outer surface 44bba is parallel to the arcuate cylindrical inner surfaces, 44aaa and 44aab. In an exemplary

embodiment, the arcuate cylindrical outer surface 44cb is inclined relative to the arcuate cylindrical inner surface 44ca.

A plurality of lower expansion cone segments 46 are interleaved among, and overlap, the upper expansion cone segments 44 and the cam arms 38c of the lower 5 cam assembly 38. In this manner, torque loads may be transmitted between the upper and lower expansion cone segments, 44 and 46. Each of the lower expansion cone segments 46 include inner portions 46a having arcuate cylindrical inner surfaces, 46aaa and 46aab, and an arcuate cylindrical outer surface 46ab, intermediate portions 46b extending from the interior portions that have an arcuate conical inner surface 10 46ba and arcuate cylindrical and spherical outer surfaces, 46bba and 46bbb, and outer portions 46c having arcuate cylindrical inner and outer surfaces, 46ca and 46cb. In an exemplary embodiment, the outer surfaces 46ab of the inner portions 46a of the upper expansion cone segments 46 define hinge grooves 46aba.

The arcuate inner cylindrical surfaces 46aaa mate with and receive the lower 15 mandrel 34, the arcuate inner cylindrical surfaces 46aab mate with and receive the arcuate cylindrical outer surfaces 38ccb of the outer portions 38cc of the corresponding cam arms 38c of the upper cam assembly 38, and the arcuate inner conical surfaces 46ba mate with and receive the arcuate conical outer surfaces 38cbb of the intermediate portions 38cb of the corresponding cam arms of the lower cam assembly.

20 In an exemplary embodiment, the radius of curvature of the arcuate cylindrical inner surface 46aaa is less than the radius of curvature of the arcuate cylindrical inner surface 46aab. In an exemplary embodiment, the radius of curvature of the arcuate cylindrical inner surface 46ca is greater than the radius of curvature of the arcuate cylindrical surface 46aab. In an exemplary embodiment, the arcuate cylindrical inner surfaces, 46aaa and 46aab, are parallel. In an exemplary embodiment, the arcuate cylindrical outer surface 46ab is inclined relative to the arcuate cylindrical inner surface 46aaa. In an exemplary embodiment, the arcuate cylindrical outer surface 46bba is parallel to the arcuate cylindrical inner surfaces, 46aaa and 46aab. In an exemplary embodiment, the arcuate cylindrical outer surface 46cb is inclined relative to the 25 30 arcuate cylindrical inner surface 46ca.

In an exemplary embodiment, the geometries of the upper and lower expansion cone segments 44 and 46 are substantially identical. In an exemplary embodiment, the upper expansion cone segments 44 are tapered in the longitudinal direction from the ends of the intermediate portions 44b to the ends of the outer portions 44c, and the

lower expansion cone segments 46 are tapered in the longitudinal direction from the ends of the intermediate portions 46b to the ends of the outer portions 46c. In an exemplary embodiment, when the upper and lower expansion segments, 44 and 46, are positioned in a fully expanded position, the arcuate cylindrical outer surfaces,

- 5 44bba and 46cb, of the upper and lower expansion cone segments define a contiguous cylindrical surface, the arcuate spherical outer surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments define an contiguous arcuate spherical surface, and the arcuate cylindrical outer surfaces, 44cb and 46bba, of the upper and lower expansion cone segments define a contiguous cylindrical surface.

- 10 An end of a lower retaining sleeve 48 defines a passage 48a for receiving and mating with the outer circumferential surfaces of the external flange 40aa and the meshing teeth 40b of the lower cam assembly 40, and an inner annular recess 48b, and includes an internal flange 48c for retaining the external flange of the lower cam assembly, and an internal flange 48d at one end of the lower retaining sleeve that
- 15 includes a rounded interior end face for mating with the hinge grooves 46 aba of the lower expansion cone segments 46 thereby pivotally coupling the lower expansion cone segments to the lower retaining sleeve. An o-ring seal 50 is received within the annular recess 48b. A disc shaped shim 49 is positioned within the lower retaining sleeve 48 between the opposing end faces of the internal flange 48c of the retaining
- 20 sleeve and the external flange 40aa of the lower cam assembly 40.

- 25 In an exemplary embodiment, the arcuate cylindrical outer surfaces 44bba of the upper expansion cone segments 44 and the arcuate cylindrical outer surfaces 46cb of the lower expansion cone segments 46 are aligned with the outer surface of the upper retaining sleeve 42. In an exemplary embodiment, the arcuate cylindrical outer surfaces 44cb of the upper expansion cone segments 44 and the arcuate cylindrical outer surfaces 46 bba of the lower expansion cone segments are aligned with the outer surface of the lower retaining sleeve 48.

- 30 An end of a float shoe adaptor 50 that includes a plurality of circumferentially spaced apart meshing teeth 50a for engaging the meshing teeth 40b of the lower cam assembly 40 is received within and threadably coupled to an end of the lower retaining sleeve 48 that defines a passage 50b at one end for receiving an end of the lower mandrel 34, a passage 50c having a reduced inside diameter at another end, a plurality of radial passages 50d at the other end, and includes an internal flange 50e, and a torsional coupling 50f at the other end that includes a plurality of torsional coupling

members 50fa. During operation, the meshing teeth 40b of the lower cam assembly 40 transmit torque loads to and from the meshing teeth 50a of the float shoe adaptor.

An end of a retaining sleeve 52 abuts the end face of the tubular base 40a of the lower cam assembly 40 and is received within and mates with the passage 50b of the float shoe adaptor 50 that defines a passage 52a for receiving an end of the lower mandrel 34, a throat passage 52b including a ball valve seat 52c, and includes a flange 52d, and another end of the retaining sleeve, having a reduced outside diameter, is received within and mates with the passage 50c of the float shoe adaptor 50.

A stop nut 54 receives and is threadably coupled to the end of the lower mandrel 34 within the passage 52a of the retaining sleeve 52, and shear pins 56 releasably couple the stop nut 54 to the retaining sleeve 52. Locking dogs 58 are positioned within an end of the retaining sleeve 52 that receive and are releasably coupled to the lower mandrel 34, and a disc shaped adjustment shim 60 receives the lower mandrel 34 and is positioned within an end of the retaining sleeve 52 between the opposing ends of the tubular base 40a of the upper cam assembly 40 and the locking dogs 58. Burst discs 62 are releasably coupled to and positioned within the radial passages 50d of the float shoe adaptor 50.

An end of a float shoe 64 mates with and is releasably coupled to the torsional coupling members 50fa of the torsional coupling 50f of the float shoe adaptor 50 that defines a passage 64a and a valveable passage 64b. In this manner torsional loads may be transmitted between the float shoe adaptor 50 and the float shoe 64. An end of an expandable tubular member 66 that surrounds the tubular support member 12, the safety collar 14, the upper mandrel collar 18, the upper packer cup 24, the lower packer cup 28, the lower mandrel 34, the upper expansion cone segments 44, the lower expansion cone segments 46, and the float shoe adaptor 50, is coupled to and receives an end of the float shoe 64 and is movably coupled to and supported by the arcuate spherical external surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments, 44 and 46.

During operation, as illustrated in Figs. 1a and 1b, the apparatus 10 is at least partially positioned within a preexisting structure such as, for example, a borehole 100 that traverses a subterranean formation that may include a preexisting wellbore casing 102. The borehole 100 may be oriented in any position, for example, from vertical to horizontal. A fluidic material 104 is then injected into the apparatus 10 through the passages 12a, 14a, 22a, 34c, 50c, 64a, and 64b into the annulus between the

expandable tubular member 66 and the borehole 100. In an exemplary embodiment, the fluidic material 104 is a hardenable fluidic sealing material. In this manner, an annular sealing layer may be formed within the annulus between the expandable tubular member 66 and the borehole 100.

- 5 As illustrated in Figs. 10a and 10b, a ball 106 is then be positioned within and blocking the valveable passage 64b of the float shoe 64 by injecting a fluidic material 108 into the apparatus 10 through the passages 12a, 14a, 22a, 34c, and 50c. As a result, the increased operating pressure within the passage 50c bursts open the burst discs 62 positioned within the radial passages 50d of the float shoe adaptor 50. The
- 10 continued injection of the fluidic material 108 thereby pressurizes the interior of the expandable tubular member 66 below the lower packer cup 28 thereby displacing the upper and lower expansion cone segments, 44 and 46, upwardly relative to the float shoe 64 and the expandable tubular member 66. As a result, the expandable tubular member 66 is plastically deformed and radially expanded. Thus, the burst discs 62
- 15 sense the operating pressure of the injected fluidic material 108 within the passage 50c and thereby control the initiation of the radial expansion and plastic deformation of the expandable tubular member 66.

In an exemplary embodiment, any leakage of the pressurized fluidic material 108 past the lower packer cup 28 is captured and sealed against further leakage by the upper packer cup 24. In this manner, the lower packer cup 28 provides the primary fluidic seal against the interior surface of the expandable tubular member 66, and the upper packer cup 24 provides a secondary, back-up, fluidic seal against the interior surface of the expandable tubular member. Furthermore, because the lower packer cup 28 and/or the upper packer cup 24 provide a fluid tight seal against the interior surface of the expandable tubular member 66, the upper and lower expansion cone segments, 44 and 46, are pulled upwardly through the expandable tubular member by the axial forces created by the packer cups.

In an exemplary embodiment, during the radial expansion process, the interface between the arcuate spherical external surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments, 44 and 46, and the interior surface of the expandable tubular member 66 is not fluid tight. As a result, the fluidic material 108 may provide lubrication to the entire extent of the interface between the cylindrical external surfaces, 44bba and 46cb, and the arcuate spherical external surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments, 44 and 46, and the interior surface of the

expandable tubular member 66. Moreover, experimental test results have indicated the unexpected result that the required operating pressure of the fluidic material 108 for radial expansion of the expandable tubular member 66 is less when the interface between the cylindrical external surfaces, 44bba and 46cb, and the arcuate spherical external surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments, 44 and 46, and the interior surface of the expandable tubular member 66 is not fluid tight. Furthermore, experimental test results have also demonstrated that the arcuate spherical external surface provided by the arcuate spherical external surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments, 44 and 46, provides 10 radial expansion and plastic deformation of the expandable tubular member 66 using lower operating pressures versus an expansion cone having a conical outer surface.

In an exemplary embodiment, as illustrated in Figs. 11a, 11b, 12, 13, 14, 15, and 16, the upper and lower expansion cone segments, 44 and 46, may then be adjusted to a collapsed position by placing a ball 110 within the ball valve seat 52c of 15 the throat passage 52b of the retaining sleeve 52. The continued injection of the fluidic material 108, after the placement of the ball 110 within the ball valve seat 52c, creates a differential pressure across the ball 110 thereby applying a downward longitudinal force onto the retaining sleeve 52 thereby shearing the shear pins 56. As a result, the retaining sleeve 52 is displaced in the downward longitudinal direction relative to the 20 float shoe adaptor 50 thereby permitting the locking dogs 58 to be displaced outwardly in the radial direction. The outward radial displacement of the locking dogs 58 disengages the locking dogs from engagement with the lower mandrel 34. Thus, the shear pins 56 sense the operating pressure of the injected fluidic material 108 within the throat passage 52b and thereby controlling the initiation of the collapsing of the 25 upper and lower expansion cone segments, 44 and 46.

The continued injection of the fluidic material 108 continues to displace the retaining sleeve 52 in the downward longitudinal direction relative to the float shoe adaptor 50 until the external flange 52d of the retaining sleeve 52 impacts, and applies a downward longitudinal force to, the internal flange 50e of the float shoe adaptor. As 30 a result, the float shoe adaptor 50 is then also displaced in the downward longitudinal direction relative to the lower mandrel 34. The downward longitudinal displacement of the float shoe adaptor 50 relative to the lower mandrel 34 causes the lower cam assembly 40, the lower expansion cone segments 46, and the lower retaining sleeve 48, which are rigidly attached to the float shoe adaptor, to also be displaced

downwardly in the longitudinal direction relative to the lower mandrel 34, the upper cam assembly 38, and the upper expansion cone segments 44.

The downward longitudinal displacement of the lower cam assembly 40 relative to the upper expansion cone segments 44 causes the upper expansion cone segments

- 5 to slide off of the conical external surfaces 40ccb of the lower cam assembly and thereby pivot inwardly in the radial direction about the internal flange 42d of the upper retaining sleeve 42. The downward longitudinal displacement of the lower expansion cone segments 46 relative to the upper cam assembly 38 causes the lower expansion cone segments 46 to slide off of the external conical surfaces 38ccb of the upper cam assembly 38 and thereby pivot inwardly in the radial direction about the internal flange 48d of the lower retaining sleeve. As a result of the inward radial movement of the upper and lower expansion cone segments, 44 and 46, the arcuate external spherical surfaces, 44bbb and 46bbb, of the upper and lower expansion cone segments, 44 and 46, no longer provide a substantially contiguous outer arcuate spherical surface.

- 15 15 The downward longitudinal movement of the retaining sleeve 42 and float shoe adaptor 50 relative to the lower mandrel 34 is stopped when the stop nut 54 impacts the locking dogs 58. At this point, as illustrated in Figs. 17a and 17b, the apparatus 10 may then be removed from the interior of the expandable tubular member 66.

- 20 Thus, the apparatus 10 may be removed from the expandable tubular member 66 prior to the complete radial expansion and plastic deformation of the expandable tubular member by controllably collapsing the upper and lower expansion cone segments, 44 and 46. As a result, the apparatus 10 provides the following benefits: (1) the apparatus is removable when expansion problems are encountered; (2) lower expansion forces are required because the portion of the expandable tubular member 25 66 between the packer cups, 24 and 28, and the expansion cone segments is exposed to the expansion fluid pressure; and (3) the expansion cone segments can be run down through the expandable tubular member, prior to radial expansion, and then the expansion cone segments can be expanded.

- 30 In several alternative embodiments, resilient members such as, for example, spring elements are coupled to the upper and lower expansion cone segments, 44 and 46, for resiliently biasing the expansion cone segments towards the expanded or collapsed position.

In several alternative embodiments, the placement of the upper and lower expansion cone segments, 44 and 46, in an expanded or collapsed position is reversible.

5 In several alternative embodiments, a small gap is provided between the upper and lower expansion cone segments, 44 and 46, when positioned in the expanded condition that varies from about .005 to .030 inches.

Turning back to Fig. 10a, as previously discussed, the lower packer cup 28 may be used to provide a primary fluidic seal against the interior surface of the expandable tubular member 66, and the upper packer cup 24 provides a secondary, back-up, 10 fluidic seal against the interior surface of the expandable tubular member. Furthermore, because the lower packer cup 28 and/or the upper packer cup 24 provide a fluid tight seal against the interior surface of the expandable tubular member 66, when the region is pressurized, the upper and lower expansion cone segments, 44 and 15 46, are pulled upwardly through the expandable tubular member by the axial forces created by the packer cups.

The packer cups may be made from an elastomer, the type of which depends on design pressures, fluids and temperatures. In several embodiments, the packer cups 24 and 28 are coupled to annular reinforcing elements or supports which are bonded to the elastomer to hold the elastomer in place when running in and out of the 20 casing and when pressurized. Conventionally, the support may be wire or a single insert, such as used in the "TP" cup from Halliburton of Duncan, Oklahoma. The support may be more complicated, for instance, it may comprise a bushing and a plurality of overlapping springs, such as used in the GW-HD cup from Guiberson Oil Tools of Alberta Canada.

25 Conventional packer cups are intended to remain stationary when pressurized. Any significant movement of a conventional packer cup when the cup has been pressurized may destroy the packer cup. Additionally, conventional packer cups may not be designed to hold the high pressures necessary for a casing expansion when moving through the casing. Pressure cycling and movement which occurs during 30 casing expansion procedures may cause degradation of the elastomer and the bond between the elastomer and inserts. Eventually the elastomer disintegrates and the packer cup is unable to hold pressure. What is needed, therefore is a packer cup which can withstand the movement and pressures associated with the casing expansion procedure.

Turning now to Fig. 18, one side of a conventional cup seal or packer cup 70 is illustrated in detail. The opposing side is symmetrical about the center line of the packer cup. In the illustrated configuration, the packer cup 70 is shown located outside of the casing. Therefore, dashed lines represent the position of an expandable 5 casing 71 relative to the packer cup 70. The packer cup 70 may be used as the upper packer cup 24 or lower packer cup 28 as described previously in reference to Figs. 1a and 10a. In several alternative embodiments, the central mandrel 72 has an external flange 74, which may provide longitudinal support for a retaining sleeve or adjusting 10 ring 76. The adjusting ring 76 receives and is coupled to the central mandrel 72. A spacer sleeve 78 also receives and is coupled to the central mandrel 72 and is longitudinally positioned between the packer cup 70 and the adjusting ring 76. In several embodiments, the adjusting ring 76 threadingly engages the spacer sleeve 78 so that the longitudinal position of the spacer sleeve may be adjusted by rotating the 15 spacer sleeve relative to the adjusting ring 76. In turn, the spacer sleeve 78 longitudinally positions and supports the packer cup 70.

In several exemplary embodiments, the packer cup 70 comprises one or more springs 80a and 80b which are bonded to and radially support an elastomeric sealing cup 82 to form a cup assembly 83. The elastomeric sealing cup 82 is generally conical in shape, having a substantially unrestricted lip portion 85 for sealingly engaging the 20 interior ID of the expandable casing 71. Opposite the lip portion 85 is a base portion 87 which is supported by a conical bushing 84 positioned between the interior side of the cup assembly 83 and the central mandrel 72. A radial thimble 86 surrounds the base portion 87 of the cup assembly 83. The radial thimble 86 has an exterior diameter which is smaller than the interior diameter of the casing by a distance "A." In the 25 embodiment illustrated in Fig. 18, the elastomeric sealing cup 82 is unsupported in a region "B" which may be generally defined as the region between a support, such as a radial thimble 86, and a point of contact "C" with the expandable casing 71.

Fig. 19a illustrates an alternative embodiment of a packer cup 90. In several exemplary embodiments, the packer cup 90 comprises one or more springs 92a and 30 92b which are bonded to and radially support an elastomeric sealing cup 94 to form a cup assembly 95. The elastomeric sealing cup 94 is generally conical in shape, having a substantially unrestricted lip portion 93 for sealingly engaging the interior ID of the expandable casing 71. Opposite the lip portion 93 is a base portion 97 which is supported by a conical bushing 96 positioned between the cup assembly and the

central mandrel 72. The supported end of the cup assembly 95 is surrounded by a radial thimble 98. The radial thimble 98 has an exterior diameter which is slightly smaller than the interior diameter, causing the distance "A" to be reduced when compared to a conventional packer cup, such as illustrated in Fig. 18.

- 5 In the embodiment illustrated in Fig. 19a, the elastomeric sealing cup 94 is unsupported in a region "B" which may be generally defined as the region between a support, such as the radial thimble 98, and a point of contact "C" with the expandable casing 71. In this embodiment, the longitudinal length of the radial thimble 98 has been increased, which reduces the unsupported region "B" of the elastomeric sealing cup 94
10 when compared to a conventional packer cup.

Reducing the length "B" of the unsupported region and the distance "A" between the exterior diameter of the thimble 98 and the ID of the casing limits movement of the elastomeric sealing cup 94 when the packer cup is pressurized. This reduced movement improves the durability of the packer seal under greater pressures
15 than conventional packer cups.

Fig. 19b illustrates an alternative embodiment of a packer cup 100. In several exemplary embodiments, the packer cup 100 comprises one or more springs 102a and 102b which are bonded to an elastomeric sealing cup 104 to form a cup assembly 105. The elastomeric sealing cup 104 is generally conical in shape, having a substantially
20 unrestricted lip portion 103 for sealingly engaging the interior ID of the expandable casing 71. Opposite the lip portion 103 is a base portion 107 which is supported by a conical bushing 106 positioned between the elastomeric seal 104 and the central mandrel 72. A pliant backup member 108 is positioned between the elastomeric sealing cup 104 and a radial thimble 110. The backup member 108 may be made from any
25 suitable pliant material, such as a fluoropolymer or fluoroelastomer (e.g., Teflon or PEEK). The use of the backup member 108 significantly reduces the unsupported region of the elastomeric sealing cup 104. Additionally, the backup member 108 easily extrudes when pressurized to expand into any gap between the outside diameter of the backup support and the ID of the casing providing a secondary seal.

30 The radial thimble 110 is similar to the radial thimble 98 (Fig. 19a) in that it has an exterior diameter which is slightly smaller than the interior diameter, causing the distance "A" to be reduced. Similarly, the longitudinal length of the radial thimble 110 has been increased which reduces the unsupported length of the elastomeric sealing cup. Reducing the unsupported region of the elastomeric sealing cup and the distance

between the exterior diameter of the thimble 98 and the ID of the casing limits movement of the elastomeric sealing cup 94 when the packer cup is pressurized. This reduced movement improves the durability of the packer seal.

Fig. 19c illustrates an alternative embodiment of a packer cup 120. In several exemplary embodiments, the packer cup 120 comprises one or more springs 122a and 122b which are bonded to an elastomeric sealing cup 124 to form a cup assembly 125. The elastomeric sealing cup 124 is generally conical in shape, having a substantially unrestricted lip portion 123 for sealingly engaging the interior ID of the expandable casing 71. Opposite the lip portion 123 is a base portion 127 which is supported by a 10 conical bushing 126 positioned between the elastomeric sealing cup 124 and the central mandrel 72. A pliant backup member 128 is positioned between the elastomeric sealing cup 124 and a radial shoe 130. The backup member 128 may be made from any suitable pliant material, such as a fluoropolymer or fluoroelastomer (e.g., Teflon or PEEK). Additionally, the backup member 128 extrudes when 15 pressurized to expand into a gap between the outside diameter of the backup member 128 and the ID of the casing. However, the use of the radial shoe 130 and the cross-sectional shape of the backup member 128 reduces the degree of extrusion when compared to packer cup 100 (Fig. 19b).

The radial shoe 130 may be made from steel or another harden material to 20 provide support and protection for the pliant backup member 128. The pliant backup member 128 reduces the unsupported length of the elastomeric sealing cup 124 which limits the movement of the elastomeric sealing cup 124 when the packer cup is pressurized. This reduced movement improves the durability of the packer cup.

Fig. 19d illustrates an alternative embodiment of a packer cup 140. In several exemplary embodiments, the packer cup 140 comprises one or more springs 142a and 142b which are bonded to an elastomeric sealing cup 144 to form a cup assembly 145. The elastomeric sealing cup 144 is generally conical in shape, having a substantially unrestricted lip portion 143 for sealingly engaging the interior ID of the expandable casing 71. Opposite the lip portion 143 is a base portion 149 which is supported by a 30 conical bushing 146 positioned between the elastomeric sealing cup 144 and the central mandrel 72. A support member 147 provides additional stiffness and support by surrounding the supported end of cup assembly 145. The support member 147 may be made of steel or another suitable material. The use of the support member 147 provides a stiff support for the elastomeric sealing cup 144 which reduces the

movement of the elastomeric sealing cup 144. Similar to the packer cup 120 discussed in reference to Fig. 19c, a pliant backup member 148 is positioned between the support member 147 and a radial shoe 150. The backup member 148 extrudes when pressurized to expand into a gap between the outside diameter of the backup support 5 and the ID of the casing. However, the use of the radial shoe 150 reduces the degree of extrusion when compared to packer cup 100 (Fig. 19b).

The radial shoe 150 may be made from steel or another harden material to provide support and protection for the pliant backup member 148. The use of a pliant backup member 148 also reduces the unsupported region of the elastomeric sealing 10 cup 144 which limits the movement of the elastomeric sealing cup 144 when the packer cup is pressurized. This reduced movement improves the durability of the packer cup.

Fig. 19e illustrates an alternative embodiment of a packer cup 160. In several exemplary embodiments, the packer cup 160 comprises one or more springs 162a and 15 162b which are bonded to an elastomeric sealing cup 164 to form a cup assembly 165. The elastomeric sealing cup 164 is generally conical in shape, having a substantially unrestricted lip portion 163 for sealingly engaging the interior ID of the expandable casing 71. Opposite the lip portion 163 is a base portion 167 which is supported by a conical bushing 166 positioned between the elastomeric sealing cup 20 164 and the central mandrel 72. The supported end of the cup assembly is also surrounded by a radial thimble 168.

In this embodiment, the elastomeric sealing cup 164 has additional elastomeric material molded proximate to the radial thimble 168 at a point "D". Because of the use 25 of additional elastomeric material and a longer longitudinal length of the radial thimble 98, the unsupported region of the elastomeric sealing cup 164 is significantly reduced. Reducing the unsupported region of the elastomeric sealing cup 164 and the distance 30 between the exterior diameter of the thimble 168 and the ID of the casing 71 limits movement of the elastomeric sealing cup 164 when the packer cup is pressurized. Additionally, the radial thimble 168 has an exterior diameter which is slightly smaller than the interior diameter, causing the gap between the radial thimble 168 and the ID of the casing 71 to be reduced. The reduced gap also limits movement of the elastomeric sealing cup 164. This reduced movement improves the durability of the packer seal.

Although illustrative embodiments of the invention have been shown and described, a wide range of modification, changes and substitution is contemplated in the foregoing disclosure. Accordingly, it is appropriate that the appended claims be construed broadly.

CLAIMS

1. A packer cup apparatus comprising:
 - 5 a central mandrel,
 - a sealing cup comprising
 - a substantially unrestricted lip for sealingly engaging a tubular member, and
 - a base portion for sealingly engaging the central mandrel,
 - a thimble positioned longitudinally along the central mandrel and surrounding the
 - 10 base portion of the sealing cup,
 - a pliant backup member positioned between the protecting member and the sealing cup,
 - a conical bushing positioned partially between the sealing cup and the central mandrel for supporting the base portion of the sealing cup,
 - 15 wherein the sealing cup further comprises an unsupported portion between the thimble and a point of engagement with the expandable tubular member, and a means for reducing the unsupported portion of the sealing cup.
2. The apparatus of claim 1 wherein the pliant backup member is made from a material selected from the group consisting of fluoropolymer, fluoroelastomer, Teflon, or PEEK.
3. The apparatus of claim 1 further comprising a restraining member surrounding the base portion of the sealing cup for restraining the sealing cup.
